1.5.3	1.6.0	01/10/2018	<ul style="list-style-type: none"> <li>• Adapter trimming: The user can now optionally provide a pre-defined adapter 3' adapter sequence. Note: In contrast to previous versions the option <code>-trim</code> now expects a value which is <u>either</u> a defined adapter sequence <u>or</u> a '?' if the adapter sequence is unknown.</li> <li>• unitas will create simplified miRNA and tRNA count tables were different sequences from the identical source (miRNA gene or tRNA) are grouped.</li> <li>• unitas will produce beautiful HTML image files for sequence read length distribution, positional nucleotide composition, 5' overlaps (option <code>-pp</code>) and ping-pong matrix (option <code>-pp</code>).</li> <li>• We added a standard t-test for the differential expression module. Note that the standard t-test is much stricter compared to SAND and it is almost impossible to get significant results after correction for alpha-error.</li> </ul>
1.6.0	1.6.1	15/10/2018	<ul style="list-style-type: none"> <li>• updated internal links.</li> </ul>
1.6.1	1.6.2	24/01/2019	<ul style="list-style-type: none"> <li>• updated internal links.</li> </ul>
1.6.2	1.7.0	07/02/2019	<ul style="list-style-type: none"> <li>• Output file "<code>unitas.full_annotation_matrix.txt</code>" contains coordinates of the small RNA relative to its source. It is now possible to define the minimum length of a tRNA-half which was previously fixed to 30nt (that is now the default value). For 5' and 3' tRNA fragments you can optimally allow more distance to the 5' and 3' end of the source tRNA (default value is still 0).</li> </ul>
1.7.0	1.7.1	03/04/2019	<ul style="list-style-type: none"> <li>• Automatically replace U with T in custom reference sequence file(s).</li> </ul>
1.7.1	1.7.2	08/04/2019	<ul style="list-style-type: none"> <li>• bug fixed: Making of some html files failed when using the option <code>-pp</code>. No more need to use option <code>-refseq</code> when using both <code>-species x</code> and <code>-skip_mapping</code>.</li> </ul>

1.7.2	1.7.3	12/04/2019	• bug fixed: With v.1.6.0 we introduced an error in the DE module which searched for FASTA input files in a wrong directory.
1.7.3	1.7.4	31/05/2019	• updated internal links.
1.7.4	1.7.5	15/07/2019	• Bug fixed: Error when importing custom reference sequences (introduced with v.1.7.1).

## 1. Scope

`unitas` is a convenient tool for small non-coding RNA (sncRNA, typically ~18-40 nt in length) annotation using Next Generation Sequencing data. `unitas` uses latest sequence information from publicly available online databases to annotate user input sequences. No installation, no further prerequisites; it runs out-of-the-box on all popular platforms (Linux, MacOS, Windows) and can be started with one simple command from the command line (terminal).

## 2. Getting started

### 2.1 General remarks

All you need to start is a sequence file in FASTA or FASTQ format, or alternatively a map file in SAM or ELAND3 format (produced by SeqMap when using the option `/output_all_matches`, or by default by sRNAmapper), and a local copy of `unitas`. You can run the stand-alone `unitas` executable file (precompiled versions are available for Linux, MacOS and Windows) on your local machine without installation or any further requirements. Running the `unitas` Perl script on your local machine requires the installation of a Perl interpreter. Perl is pre-installed on common Linux and Mac systems. For Windows you can download and install a free Perl distribution such as StrawberryPerl ([www.strawberryperl.com](http://www.strawberryperl.com)) or ActivePerl ([www.activestate.com/activeperl/downloads](http://www.activestate.com/activeperl/downloads)). When running `unitas` for the first time you need a connection to the internet in order to allow `unitas` to download a set of latest reference sequences. Subsequent runs can use previously downloaded data. You can start `unitas` from the command line (terminal) using the following command:

#### STAND-ALONE EXECUTABLES

##### Windows

```
unitas.exe -input sequence_or_map.file -species genus_species
```

##### MacOS or Linux

```
./unitas -input sequence_or_map.file -species genus_species
```

#### PERL SCRIPTS

##### Windows, MacOS or Linux

```
perl unitas.pl -input sequence_or_map.file -species genus_species
```

By default, `unitas` will not open more than one thread and multiple input files will be processed one after the other. We recommend to use the option `-threads [integer]` if more than one CPU core is available (which should be the case on most modern computers). During computation, `unitas` creates temporary files named, e.g., `-5388.unitas_pid` according to the process IDs of each forked process. `unitas` uses these temporary files to control the maximum number of parallel processes. Though this may not be the most sophisticated solution for this task, it is one that does not require the installation of additional Perl modules such as `Parallel::ForkManager` which are probably not part of a standard Perl distribution. You should not remove or rename these files while `unitas` is running. The files will be removed automatically when the annotation process for the input file is finished. You should also not run several instances of `unitas` in same directory.

## 2.2 Examples

### 2.2.1 Trim adapter sequences

You want to analyze sequence data from other people that still contains 3' adapters but you are not sure which 3' adapters they used for library preparation. Let `unitas` find and trim adapters automatically:

```
perl unitas.pl -input map.file -species genus_species -trim ?
```

Of course you can provide the adapter sequence if you know it:

```
perl unitas.pl -input map.file -species genus_species -trim TGGAATCTC
```

We do not recommend to provide the whole 3' adapter sequence. Just take the first 10 or 12 adapter bases from the 5' end of the adapter and unitas will trim all the rest.

### 2.1.2 Find (21nt and 24nt) phasiRNAs

You are a plant guy and have a small RNA map file in SAM or ELAND3 format. You want to find phasiRNAs and their source loci without doing all the other stuff (sequence annotation):

```
perl unitas.pl -skip_mapping -input map.file -phasi 21 -phasi 24
```

### 2.1.3 You want to annotate small RNAs from a 'non-Ensembl species'

You are lucky and there is a closely related species supported by unitas:

```
perl unitas.pl -input sequence_or_map.file -species related_species
```

or

Bad luck, there is no closely related species supported, but you have a set of reference sequences you want to use:

```
perl unitas.pl -input sequence_or_map.file -species x -refseq user_reference.fasta
```

### 2.1.4 You want to calculate ping-pong signatures and ping-pong matrixes

You are one of those piGuys and are interested in ping-pong signatures, particularly for those reads that are not fragments of any other non-coding RNA class:

```
perl unitas.pl -input map.file -species genus_species -pp
```

## 3. Workflow

### 3.1. Prior to annotation

unitas creates a data dump folder on your local machine to store reference sequences downloaded from the internet. The folder will be named UNITASrefdump\_genus\_species (e.g. UNITASrefdump\_homo\_sapiens when downloading human reference sequences). If present, subsequent annotation runs will use the information stored in this folder. You can force unitas to download the latest reference sequences using the option `-latest_ref`. This folder will contain a file named `db_versions.info` that provides information on database version or release date:

```
SeqMap version/date: ..... 1.0.13
Genomic tRNA database version/date: ... 30.05.2017 (dd.mm.yyyy)
piRNA cluster database version/date: .. 30.05.2017 (dd.mm.yyyy)
Ensembl version/date: ..... Release 88
EnsemblGenomes version/date: ..... Release 35
tRF-1 sequence data version/date: ..... 30.05.2017 (dd.mm.yyyy)
tRNA-leader sequence data version/date: 30.05.2017 (dd.mm.yyyy)
SILVA rRNA (SSU) database version/date: Release 128.1
SILVA rRNA (LSU) database version/date: Release 128.1
miRBase database version/date: ..... Release 21
```

#### 3.1.1 Input file check and conversion

unitas will check the format of the input file(s) which must be provided in FASTA, FASTQ, SAM or ELAND3 format. You should not use multiple files with identical names from different folders. Input files will be converted into FASTA format. unitas uses collapsed input files in FASTA format as this greatly reduces computation time. Collapsed input files contain only non-identical sequences with FASTA headers referring to read counts of each sequence. If necessary, unitas will automatically collapse the input files provided by the user, e.g.:

```
>SRR029124.2054760 WICMT-SOLEXA_309ETAAXX:2:43:1367:1703 length=18
AGCGTG TAGGGATCCAAA
>SRR029124.2054761 WICMT-SOLEXA_309ETAAXX:2:43:1151:254 length=22
TAGCAGCACGTAATATTGGCG
>SRR029124.2054763 WICMT-SOLEXA_309ETAAXX:2:43:1785:135 length=18
AGCGTG TAGGGATCCAAA
```

will be collapsed to:

```
>2
AGCGTG TAGGGATCCAAA
>1
TAGCAGCACGTAATATTGGCG
```

In addition to reference sequences from online databases, the user can provide an arbitrary number of additional sequence files in FASTA format that will be used for sequence annotation (use the option `-refseq [sequence.file]`). The FASTA headers should have the following format:

```
>ncRNA_class|ncRNA_name
```

Where the ncRNA class (e.g. tRNA) is separated from its name (e.g. tRNA-Gly-GGT) with a pipe symbol. Do not use identical FASTA headers for different sequences. `unitas` will convert FASTA headers with bad format automatically using `'refseq'` as description for ncRNA class and the original FASTA header for the ncRNA name.

### 3.1.2 3' adapter recognition and trimming

In most cases, sequence reads from NGS datasets comprise 3' adapter sequences. When using datasets from NCBI's Sequence Read Archive it can be difficult to figure out which adapter was used to create the dataset in question. When using the option `-trimm`, `unitas` screens for the most frequent 3' sequence motifs (default length = 12 nt but is adjusted automatically when sequence reads in input file are shorter). A first round of adapter trimming is then performed based on the identified motif allowing 2 mismatches for 12 nt motifs, 1 mismatch for motifs  $\leq 11$  nt and 0 mismatch for motifs  $\leq 8$  nt. If the original motif is not found within a given sequence read, `unitas` truncates the motif sequentially by one 3' nt and checks for its occurrence at the very 3' end of the sequence read until the motif is found or the motif length falls below 6 nt. Following this first round of adapter trimming, `unitas` checks the positional nucleotide composition of the trimmed sequence reads and will remove further 3' nucleotide positions in case they exceed a specified nucleotide bias (default = 0.8, change this value with the option `-trim_maxfinalbias`). Recently, a nice tool for adapter prediction named `DNApi` has been published by Tsuji and Weng (<http://dx.doi.org/10.1371/journal.pone.0164228>). Noteworthy, `unitas` and `DNApi` reported identical adapter sequences for the datasets that we have tested. However, if you prefer to use `DNApi` you can simply copy the software into the `unitas` folder. `unitas` will check for the presence of the `DNApi` Python script (`dnapi.py`) and call it with a system command. Note that there might be additional dependencies for `DNApi`, at least you should have Python installed on your computer. If, for what reason ever, adapter prediction with `DNApi` fails, `unitas` will continue adapter prediction with its own algorithm.

Relevant command line options:

option	default	explanation
<code>-trim ['?' or known adapter sequence]</code>	<code>off</code>	Apply adapter (recognition and) trimming
<code>-trim_ignore_5p [integer]</code>	22	Ignore first $n$ basepairs for 3' adapter prediction
<code>-trim_skip_reads [integer]</code>	10000	Skip the first $n$ reads when searching for frequent motifs.
<code>-trim_check_reads [integer]</code>	500000	Check $n$ reads for 3' adapter prediction.
<code>-trim_polyA</code>	<code>off</code>	Allow polyA tails as 3' adapter sequence.
<code>-trim_minlength [integer]</code>	10	Minimum length of trimmed read for further processing
<code>-trim_maxlength [integer]</code>	50	Maximum length of trimmed read for further processing
<code>-trim_maxfinalbias [floating point, 0..1]</code>	0.8	Maximum allowed 3' nucleotide bias after trimming

### 3.1.3 Low complexity filter

`unitas` can filter out low complexity sequences from the input file(s). This filter is an improved implementation of the `duster` tool provided as a part of the NGS TOOLBOX (<http://www.smallnagroup.uni-mainz.de/software/TBr2.zip>). By default, it removes sequences that consist for  $\geq 75\%$  (change default value with option `-dust_limit [fraction]`) of simple sequence repeats with a minimum motif size of 1 nt and a maximum motif size of 5 nt (change default value with option `-dust_max [integer]`). In addition, `unitas` will filter out reads

that exhibit a high fraction of N positions (default = 0.5, change this value with the option `-skip_dust`). The filtering step can be skipped using the option `-skip_dust`.

Relevant command line options:

option	default	explanation
<code>-skip_dust</code>	off	Do not filter low complexity reads
<code>-dust_limit</code> [floating point, 0..1]	0.75	Maximum allowed fraction of simple sequence motifs
<code>-dust_max</code> [integer]	5	Maximum length of a simple sequence motif
<code>-dust_maxN</code> [floating point, 0..1]	0.5	Maximum allowed fraction of N nucleotides
<code>-dust_ignore_2bases_bias</code>	off	Ignore bias for 2 bases in sequence reads

### 3.1.4 Reference sequence download

`unitas` uses publicly available reference sequences for the species in question. Automatic sequence download is supported for all species that are included in the current Ensembl release (744 species or strains, 13-MARCH-2017). For other species you should select a closely related species or use the option `-species x` and provide separate reference sequence file(s) with the option `-refseq [sequence.file]` (see 3.1.1 for correct format). `unitas` connects to the Mainz University server to get the latest list of supported species. If that fails, `unitas` uses an internal list that may vary depending on the `unitas` version you use. Latest download links are also fetched from the Mainz University server or alternatively taken from an internal list. If download of the reference sequence from the respective database fails (in case of server downtime or outdated links [links on the smallRNAgroup server are updated weekly]), `unitas` downloads the required reference sequences directly from the Mainz University server where they are updated weekly. The following online sources are used for annotation (BE FAIR: Please cite the according references in addition to `unitas` when making use of `unitas` sequence annotation):

database name	data	reference
<b>GtRNAdb</b>	genomic tRNA sequences	Chan PP, Lowe TM. GtRNAdb: A database of transfer RNA genes detected in genomic sequence. <i>Nucleic Acids Res.</i> 2009 <b>37</b> :D93-D97.

<b>piRNA cluster database</b>	genomic piRNA cluster sequences	Rosenkranz D. piRNA cluster database: a web resource for piRNA producing loci. <i>Nucleic Acids Res.</i> 2016 <b>44</b> :D223-D230.
<b>Ensembl</b>	ncRNA/cDNA collection (miRNA sequences will be removed from ncRNA data)	Yates A, Akanni W, Amode MR, Barrell D, Billis K et al. Ensembl 2016. <i>Nucleic Acids Res.</i> 2016 <b>44</b> :D710-716.
<b>miRBase</b>	miRNA (mature/precursor) sequences	Kozomara A, Griffiths-Jones S. miRBase: annotating high confidence microRNAs using deep sequencing data. <i>Nucleic Acids Res.</i> 2014 <b>42</b> :D68-D73.

### 3.1.5 SeqMap download and compilation

`unitas` uses SeqMap to perform many (not all) probe to reference mapping steps. The SeqMap source code (C++) is downloaded and compiled to an executable file via the g++ compiler which is part of most operating systems. The executable file is named `seqmap.exe` and will appear in the same directory as `unitas`, the source code is stored in the data dump folder (see 3.2.3). If compilation fails, `unitas` will download precompiled SeqMap executable from the Mainz University sever (On linux and Mac you may have to manually change file permissions in order to allow execution of the SeqMap file!). You can also manually download the files from here: <http://www-personal.umich.edu/~jianghui/seqmap/>. Save a local copy of SeqMap to the same directory as `unitas` and rename it into `seqmap.exe` (always use the extension `.exe` since `unitas` will do a system call). Please do not forget to cite the SeqMap paper when making use of `unitas` sequence annotation: Jiang H, Wong WH SeqMap: Mapping Massive Amount of Oligonucleotides to the Genome. 2008 *Bioinformatics* **24**:2395-2396.

## 3.2 The annotation process

`unitas` can process an arbitrary number of sequence files in parallel. By default, multiple input files are processed one after another. For multithreading use the option `-threads [integer]`. For each input dataset, `unitas` creates a results dump folder, which is named according to the current date and input file name (plus consecutive

numbering), e.g.: UNITAS\_01-01-2017\_input.fasta\_#1. Result files and temporary files are stored in this folder. By default, temporary files (SeqMap reports, SeqMap input/output files other reference sequence files) are removed after annotation. To keep temporary files use the option `-keep_temp`.

### 3.2.1 miRNA annotation

Mature miRNA sequences from miRBase are loaded into memory. Matches to miRNAs from the species in question and matches to miRNAs from different species will be reported separately. In the first step, `unitas` searches for perfect full length matches to mature miRNAs of the species in question (canonical miRNAs). Subsequently, non-matching sequences are mapped to miRNA precursor sequences of the species in question in order to identify non-canonical miRNAs. Still not matching sequences are trimmed at the 3' end to check whether they represent 3' tailed canonical or non-canonical miRNAs. By default, `unitas` allows up to 2 non-template 3' nucleotides. This value can be changed using the option `-tail [integer]`. Then, the same procedure is performed for the remaining sequences and miRNAs from other species. In summary, the order of miRNA annotation is:

1. **untailed canonical miRNA from the species in question**
2. **untailed non-canonical miRNA from the species in question**
3. **3' tailed canonical miRNA from the species in question**
4. **3' tailed non-canonical miRNA from the species in question**
5. untailed canonical miRNA from other species
6. untailed non-canonical miRNA from other species
7. 3' tailed canonical miRNA from other species
8. 3' tailed non-canonical miRNA from other species

Examples:

```

1.  UUCAAGUAAUCCAGGAUAGGCU
2.  UCAAGUAAUCCAGGAUAGGCU--G
3.  UUCAAGUAAUCCAGGAUAGGCCUUU
4.  UCAAGUAAUCCAGGAUAGGCU--GAA

      G       U           C           --G  CA
5'  GUG CCUCGU CAAGUAAUC AGGAUAGGCU  UG  G
    ||| ||||| ||||| ||||| ||||| ||||| ||  ||  G
3'  CGC GGGGCA GUUCAUUGG UCUUAUCCGG  AC  U
      A       C           U           GUA  CC

```

This means that, e.g., when using human input sequences, a sequence is annotated as 3' tailed canonical human miRNA instead of untailed canonical mouse miRNA, even though both alternatives are possible.

`unitas` outputs tab-delimited miRNA annotation tables (e.g. `unitas.miR-table_Human.txt` and `unitas.miR-table_non-Human.txt`) that contains the following information: miRNA name (e.g. miR-376b-3p), miRNA sequence, total number of reads, number of reads without tiling (+N0-3'), number of reads with one non-template 3' nucleotide (+N1-3') [... number of additional columns depends on the number of allowed non-template 3' nucleotides], number of A-tailed reads, number of T-tailed reads, number of G-tailed reads, number of C-tailed reads [... number of additional columns depends on the number of allowed non-template 3' nucleotides, e.g. AA-tailed reads etc.].

In addition, `unitas` outputs files (e.g. `unitas.miR-modifications_Human.txt` and `unitas.miR-modifications_non-Human.txt`) that summarize information on non-template 3' ends in the following simple format (tail, read counts):

```

3'-tailings (non-template nucleotides)
A      33596
AA     3143
AAA    855
AAC    114
AAG    347
AAT    547
[...]
```

This file also summarizes internal modifications that were identified during miRNA annotation in the following format:

```
Internal modifications (?->[ATGCN] = mapped sequence exceeds precursor sequence)
G->T 53898
C->T 13998
T->G 13514
T->C 10506
A->G 8916
T->A 6270
[...]
```

It further gives you information on the positions where modifications occur like this:

```
Positions where internal modifications occur
1 2481
2 1638
3 3030
4 1589
5 1706
6 3580
[...]
```

Finally, it provides a table that combines modifications and positions in the following style:

```
Modifications per position
      G->T  C->T  T->G  T->C  A->G  T->A  A->C  G->A  C->A  G->C
1      425   108   251   403   103   247   153   110   184   258
2      332    42    51   109   156    40   360   193    43   202
3     1047   100    69    36    90    11   175   771   167   499
4      177   263    85    39   104    17   153    60   495    67

```

Relevant command line options:

option	default	explanation
<code>-skip_miR</code>	off	Skip miRNA annotation
<code>-species_miR_only</code>	off	Skip mapping to non-species miRNAs
<code>-tail [integer]</code>	2	Maximum number of non-template 3' nucleotides
<code>-intmod [integer]</code>	1	Maximum number of internal modifications

### 3.2.2 ncRNA/mRNA fragments

Input sequences that cannot be annotated as miRNA sequence are mapped to ncRNA/cDNA sequences in sense orientation to identify fragments of larger ncRNA classes or fragments of mRNA. By default the number of allowed mismatches is 1 and the number of allowed insertions/deletions is 0. You can change the default value with the option `-mismatch [integer]` and `-insdel [integer]`, respectively. The maximum possible number of allowed mismatches is 5, the maximum possible number of allowed insertions/deletions is 3. Note that increasing the number of allowed mismatches and insertions/deletions will significantly increase memory usage and computation time. When allowing mismatches, only the best alignments in terms of mismatch counts will be considered for sequence annotation. Read counts of sequences that match different reference sequences (with equal alignment quality) are apportioned accordingly. As a result, the values for read counts per class may be decimal numbers rather than integers.

Mapping to cDNA is performed by default, but can be skipped using the option `-skip_cDNA`. Considering tRNA-derived sequences, *unitas* further classifies sequences into 5' tRFs, 5' tR-halves, 3' tRFs, 3' CCA-tRFs, 3' tR-halves, tRF1, tRNA-leader and misc-tRFs based on alignment position and sequence length (read counts for genomic and mitochondrial tRNA-derived sequences are listed separately). In addition, *unitas* creates a table (`unitas.tRF-table.txt`) that lists which fragments are processed from which tRNAs.

unitas outputs FASTA files for each class of annotated sequences (miRNAs, tRNA, rRNA etc.). Note that one sequence can occur in more than one output file if the sequence maps to different reference sequences. Sequences in the FASTA output files are sorted according to read counts in descending order, e.g.:

```
>5044
TCCCTGGTGGTCTAGTGGTTAGGATTCGGCGCT
>781
GCCCGGATAGCTCAGTCGGTAGAGCATCAGAC
>774
CGCGGGAGACCGGGGTTTCGATTCCCCGACGGG
>647
GCGCCGCTGGTGTAGTGGTATCATGCAAG
[...]
```

For sequences that map to genomic piRNA clusters, the FASTA headers contain additional information that refers to the genomic coordinates of the piRNA producing locus, e.g.:

```
>46:Chr6 4863485-4881004
TAGGCGAATCTAGGTATTTC AACGATGCA
```

The FASTA files are stored in the results dump folder (see 3.2) and are named e.g. `unitas.miR.Human.fas` when using human input sequences. Each FASTA file is accompanied by a file that contains information on length distribution and positional nucleotide composition for the sequence reads assigned to this class, e.g.:

```
LENGTH DISTRIBUTION
length reads
18      271
19      263
20      173
21      902
22     1675
23      729
24      311
[...]
```

```
POSITIONAL NUCLEOTIDE COMPOSITION
pos.   A       C       G       T
1     1963   2406   11144   7520
2     472    16896  4775    890
3     2277   13295  5735   1726
4     1613   12796  3578   5046
5     667    4171   7075   11120
6     2124   1965   17564   1380
[...]
```

The output file `unitas.annotation_summary.txt` provides a table that summarizes sequence annotation (normalized reads per class) which looks like this:

```
low_complexity          1244
miRNA                   80727
  miRNA:homo_sapiens    76338

IG_V_pseudogene	IGHVII-20-3	0.0113937832958541
IG_V_pseudogene	CH17-60O17.11	0.00377588629090349
IG_V_pseudogene	IGHVII-44-2D	0.00377588629090349
Mt_rRNA	MT-RNR1	7953.66666666667
Mt_rRNA	MT-RNR2	3363.69603174603
Mt_tRNA	MT-TF	8870.83333333333

[...]

This list is sorted alphabetically according to transcript classes (capital letters first). The order of transcripts within one class depends on the number of normalized read count.

### 3.2.3 tRNA fragments

The following figure illustrates how `unitas` classifies different tRNA fragment.

Note that there exist no databases for tRNA leader sequences or tRNA trailer sequences. Reference tRNA leader sequences used by `unitas` represent a stretch of 50bp upstream to the mature tRNA. Reference tRNA trailer sequences represent the downstream sequence of each mature tRNA until the oligo-U signal ( $U_{3/4}$ -3').

Relevant command line options:

option	default	explanation
<code>-mismatch [integer]</code>	1	Maximum number of mismatch to reference
<code>-insdel [integer]</code>	0	Maximum number of insertions/deletions
<code>-riborase</code>	off	Map sequences to a complete collection of rRNA sequences from NCBI nucleotide database. This is recommended to identify rRNA degradation products in species with low quality ncRNA annotation.
<code>-CC_is_CCA</code>	off	Treats CC-3' ends as CCA-3' ends when matching to tRNAs. Use this option when you removed poly-A tails from your raw sequences.
<code>-noCCAcheck</code>	off	Use this option if you want to map against tRNA sequences as they are deposited in the databases. By default unites will build CCA-3' ends to reference tRNA sequences.
<code>-min_tRNA_half_size</code>	30	Minimum length for a tRNA fragment to be annotated as tRNA-half instead of tRF.
<code>-max_tRNA_end_dist</code>	0	Maximum distance of a tRNA fragment from the ends of a source tRNA to be annotated as 5' or 3' fragment. Otherwise it will be annotated as misc-tRF (internal fragment).

### 3.2.3 Searching piRNA candidates

Piwi interacting RNAs (piRNAs) typically pass the described pipeline without producing a match to any known ncRNA or cDNA. Thus, non-annotated sequences (saved in the output file `unitas.no-annotation.fas`) are subsequently mapped to known piRNA producing loci of the species in question (if available). This step is performed by default, but can be skipped using the option `-skip_piR`. Searching for piRNA candidates is particularly insightful when handling data derived from germ line tissues, or tissues that were shown to contain noteworthy amounts of piRNA-like molecules (e.g. brain or epididymis). In this case, we further recommend using sequences without annotation (saved in the output file `unitas.no-annotation.fas`) for subsequent piRNA cluster prediction with proTRAC.

When using map files as input you can also search for ping-pong signatures within your sequence data. When using the option `-pp`, `unitas` will check and report the 5' overlaps of mapped sequence reads and calculate a Z-score for the enrichment of 10 bp overlaps according to Zhang et al. 2011, *Mol Cell* 44:572-584.

### 3.2.4 Searching phased small RNAs (phasiRNAs)

When using map files as input you can search for phased small interfering RNAs (phasiRNAs). Use the option `-phasi [n]` to search for phasiRNAs with length `n`. You can use the option multiple times in one command, like this:

```
-phasi 21 -phasi 24
```

If you only want to search for phased RNAs without doing all the other annotation steps before you should make use of the options `-skip_dust`, `-skip_miR`, `-skip_piR`, `-skip_cDNA` and `skip_ncRNA`.

`unitas` will scan the map file with a sliding window (default size = 1 kb) and save coordinates and read counts of putative phasiRNAs and all other mapped sequence reads. The coordinates of putative phasiRNAs (that is all reads with correct length) from plus and minus strand are unified to check for phasing on both strands. Each sliding window is subsequently analyzed for the presence of phasiRNAs with significant read count over the background. Significance is calculated based on the following formula:

$$p = 1 - \left( \sum_{k=0}^j \binom{n}{k} q^k (1-q)^{n-k} \right)$$

in which `j` refers to the observed number of reads with length `i` in a specified phase, `n` refers to the total number of reads with length `i` and `q` is given by `1/i` and refers to the probability of a read to be located in a given phase, assuming that a sequence read can map to any position within the sliding window with equal probability. `unitas` employs strict Bonferroni correction for multiple testing by means of the number of analyzed sliding windows, that

```
perl unitas.pl -diffexpr -g1 UNITAS_01-01-2017_file1.fas_#1 -g2 UNITAS_01-01-2017_file2.fas_#1
```

With the option `-g1` and `-g2` you can assign the different output folders to group 1 (`-g1`) and group 2 (`-g2`), respectively. You can use an arbitrary number of output folders for each group like this:

```
-g1 UNITAS_01-01-2017_fileA.fas_#1 -g1 UNITAS_01-01-2017_fileB.fas_#1
```

By default the results will be written into the files `unitas.diff-expr.up1` and `unitas.diff-expr.up2` where the first file lists sequences with significantly higher abundance in group 1 and the second file lists sequences with significantly higher abundance in group 2. Both files will have the following format:

sequence	abs_folder1	abs_folder2	rpm_folder1	rpm_folder2	avg_group1	avg_group2	p-value	corr_p-value	class
AAAAGAAGCTTTGAAGAGA	36	10	16.98	5.39	16.98	5.39	0.000034	0.02992343	rRNA

where the first column gives the small RNA sequence. The next columns refer to absolute read counts for this sequence in the different samples (`unitas` output folders) followed by the corresponding rpm values. The number of these columns depends on the number of input samples (`unitas` output folders). The next two columns refer to the average rpm values for samples in group 1 and samples in group 2. In this case the values are identical because there is only one sample per group (note that you should really use more than one replicate per group for this kind of analysis). The next columns refer to the raw p-value and the alpha-corrected p-value. The final column gives you information to which ncRNA class this small RNA belongs (can be more than one class).

By default, `unitas` will perform a custom statistical test which we call **SAND** (shared area of normal distributions) to detect differentially expressed small RNAs. In principal the test bases on the assumption that the number of sequence reads observed in biological replicates for one condition (variance across samples, individuals, RNA extraction- or library preparation procedures) is roughly normally distributed. To calculate the variance for one condition you should not use less than two replicates for one condition (one group). Otherwise, there is no possibility to get a reasonable estimation of the biological variance occurring between samples of the same condition. However, `unitas` will also perform tests with only one replicate, in this case using predefined minimum values of variance (standard deviation) depending on dataset size and the observed rpm value for each sequence. The predefined minimum values correspond to the standard deviation one would expect to observe when the identical dataset would be resampled randomly (e.g. doing resequencing of the same library). They are calculated according to the formula:

$$\sqrt{\frac{r^{-1}}{10^6}} \cdot a^{-1}$$

where  $r$  represents the total number of reads for a replicate and  $a$  represents the rpm value for the sequence in question. These minimal values for standard deviation are also employed when providing more than one replicate per group, which is relevant for those cases where the rpm values for one sequence in different replicates are by hazard (almost) identical. When you have no possibility to use more than one replicate for a condition (group), we recommend that you give an estimation on the deviation that you *would* expect across replicates (rather than relying on the minimum standard deviation values). You can do this using the option `-diffexpr_estdev [0..1]`. As an example, you may estimate that when you had two additional replicates, the rpm value for a given small RNA sequence could be 20% higher or 20% lower compared to the replicate that you have. In this case, you would have to use the option like this:

```
-diffexpr_estdev 0.2
```

Doing so, `unitas` will assume that rpm values can be 20% higher or lower. You can think of it as adding two virtual replicates to the group that has only one replicate, one comprising read counts 20% higher, one comprising read counts 20% lower).

Having the expectation value (average read counts across replicates) and standard deviation of rpm values across replicates, the probability density function of rpm values can be displayed according to the formula:

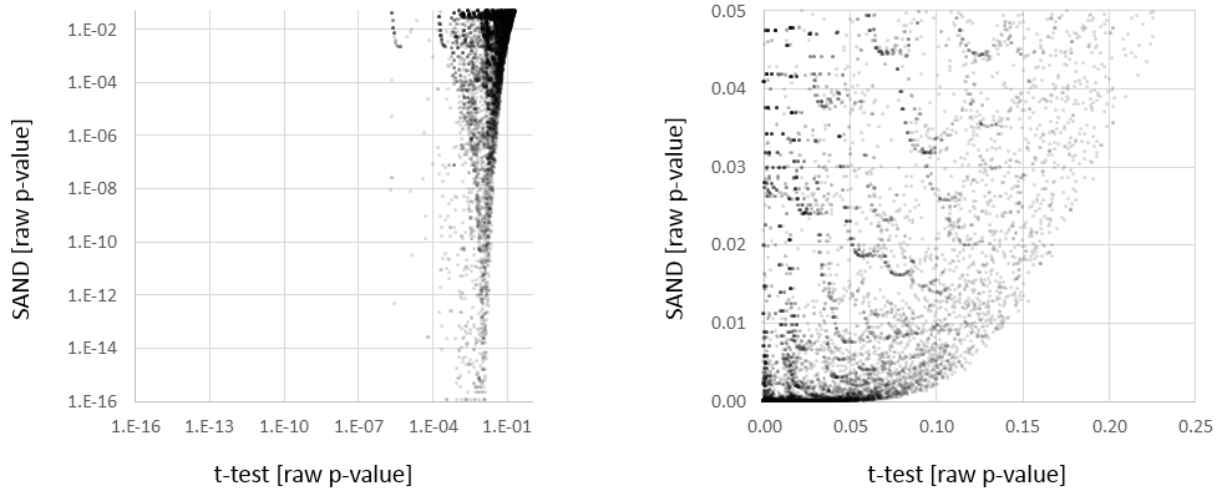

$$f(x|\mu, \sigma^2) = \frac{1}{\sqrt{2\sigma^2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where  $\mu$  is the expectation (or mean) value and  $\sigma$  is the standard deviation. When we now compare the probability density function for the same sequence across two different conditions (1 and 2) we should observe two graphs that look like this:

In theory, these graphs represent the distribution of rpm values that one would expect when we have an infinite number of replicates for each condition (x-axis: reads or rpm, y-axis: number of replicates). The shared area under both graphs (red), in relation to the area of the remaining integrals of both graphs, represents the probability to observe the same rpm values in both conditions. Accordingly, we can assume that read counts for one sequence are significantly different across two conditions when the shared area is below a critical value (e.g. 0.05, with an overall integral of 1).

Instead of using the SAND test you may prefer a **standard t-test** (unpaired, two-sided) to compare the expression of small RNAs across different conditions by using the option `-diffexpr_t`. You should note that the standard t-test is much stricter compared to our SAND test and it is almost impossible to get significant results after correction for alpha-error. Thus we recommend not to perform correction for alpha error when using the standard t-test (`-diffexpr_t -diffexpr_acorrection 0`). We performed SAND and t-test on the same set of data and compared the raw p-values for differential expression of single small RNA sequences. You will find the comparison of both test in the figure below (all sequences with  $p \leq 0.05$  according to SAND).

While there is a correlation of p-values from the two different tests, raw p-values from SAND are typically much smaller, meaning that some of them will still remain below the critical value after correction for alpha-error.

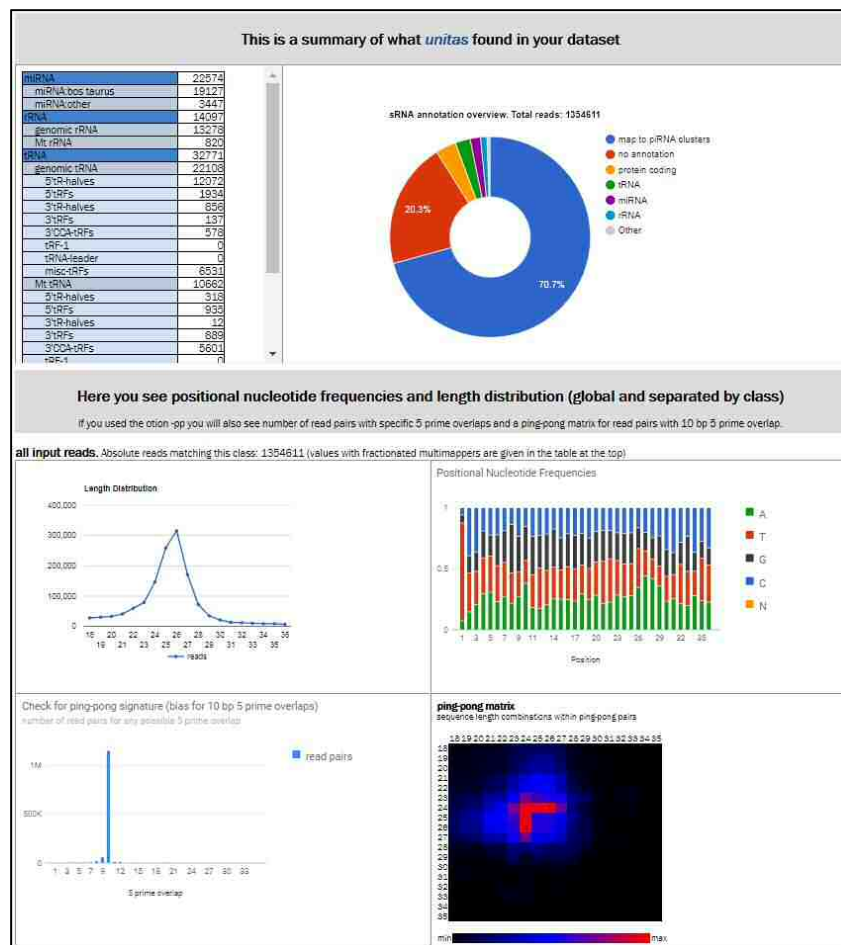

Relevant command line options:

option	default	explanation
<code>-diffexpr</code>	<code>off</code>	Search for differentially expressed small RNAs
<code>-diffexpr_t</code>	<code>off</code>	Perform standard t-test instead of SAND
<code>-diffexpr_p [floating point, 0..1]</code>	0.05	Critical p-value for differential expression
<code>-diffexpr_acorrection [0;1;2]</code>	1	Chose how to correct alpha error. 0: no correction. 1: Bonferroni-Holm procedure. 2: Strict Bonferroni correction.
<code>-diffexpr_estdev [floating point, 0..1]</code>	0.05	Estimate standard deviation when you have only one replicate for a condition.
<code>-g1 [folder name]</code>	n.a.	Specify <code>unitas</code> output folder for group 1
<code>-g2 [folder name]</code>	n.a.	Specify <code>unitas</code> output folder for group 2

## 4. Special output files

### 4.1 HTML image files

`unitas` will create a series of HTML output files showing a summary of RNA classes found in the input data, sequence read length distributions and positional nucleotide sequences. The HTML files use the Google Visualization API which required a internet connection. Note that none of your data will be uploaded to any server, but the data on your local computer will be visualized using some Java code fetched from a Google server. Each HTML figure is stored in a separate `.html` file within the `html` sub-folder. However, there is also a file named `results.html` which combines all HTML files in order to get a convenient overview of all the results. On a test dataset comprising small RNAs from cow oocytes (SAM map file, using the option `-pp`) the `results.html` file looks like this:

This file will always show a table with read counts for each RNA class together with a corresponding donut chart at the top. Below you will find sequence read length distribution and positional nucleotide frequencies for the complete input data and for each RNA class separately. If you used the option `-pp` to scan for 5' overlaps of mapped reads you will also see a chart for detected 5' overlaps (bias for 10 bp 5' overlaps = ping-pong signature) and a so-called ping-pong matrix which visualizes the frequencies of sequence lengths within ping-pong pairs (pairs of sequences with 10 bp 5' overlaps). In the example given above you see a strong enrichment for 10 bp 5' overlaps which is an indication for ongoing ping-pong amplification. By means of the ping-pong matrix you can see that most ping-pong sequence pairs combine sequences with a length of 24 nt and 26 nt (x marks the most frequent combination). Differentially sized sequences within a ping-pong pair can indicate heterotypic ping-pong amplification involving two different Piwi paralogs (see <https://www.nature.com/articles/s42003-018-0141-4> as an example how to deduce homotypic/heterotypic ping-pong amplification from ping-pong matrixes).

#### 4.2.1 unitas.tRF-table.txt

This file lists all tRNAs that were found to produce tRFs. The columns report sequence read counts for the different types of tRFs. For each tRF-type you will see fractionated and absolute values. Fractionated values account for the fact that one sequence may map to multiple mature tRNA sequences.

#### 4.2.2 unitas.tRF-table.simplified.txt

This file combines fractionated counts for the different source tRNAs. It helps you to determine the overall contribution of a specific tRNA regardless of the different types of RNA fragments. tRNAs are sorted according to read counts in descending order. The third column of this file includes counts from pre-mature tRNAs, that is including small RNAs derived from leader and trailer sequences.

tRNA_name	absolute_counts	absolute_counts_including_trailer_and_leader_of_pre-tRNA
tRNA-Gly-GCC	3706.15	3912.65
tRNA-Gly-CCC	2224.85	3054.25
tRNA-Lys-CTT	1426.7556998557	1427.35818432775
tRNA-Glu-CTC	1241.93795093795	1241.93795093795
tRNA-Asp-GTC	582.857142857143	582.857142857143
tRNA-Val-CAC	433.734521687463	471.734521687463

#### 4.3.1 unitas.miR-table\_[species].txt

This file lists all different iso-miRs detected in the input dataset. If you are rather interested in global counts per miRNA gene look at the file `unitas.miR-table_[species].simplified.txt`. Substitutions compared to the reference sequence are indicated in brackets like this: (19T->A), which means that at position 19 of the miRNAs there is a substitution from T (reference) to A. You will note that miRNA names (e.g. miR-148a-3p) may occur multiple times. However they are followed by non-identical sequences, e.g. CAGTGCACTACAGAACTTTGT and CAGTGCACTACAGAACTTTGTC, showing different iso-miRs that originate from the same miRNA gene. For each iso-miR the following columns display total reads, non-tailed reads (+N0-3'), tailed reads (+N1-3', +N2-3', depending on how much non-template 3' nucleotides you allowed during mapping. The default is 2), followed by the counts for all possible non-template 3' nucleotides.

#### 4.3.2 unitas.miR-table\_[species].simplified.txt

This file combines absolute counts for different miRNA genes like this:

miR_name	absolute_counts
miR-10b-5p	215661
let-7a-5p	87399
miR-30d-5p	61788
miR-148a-3p	60038
let-7f-5p	55226

#### 4.4 unitas.[RNAclass].ppmatrix

This file represents a matrix that gives information on scores for 10 nt 5' overlaps separated by sequence length. This means that you will see which size of sequences is responsible for a putative ping-pong signal. Converted into

an image, you may observe one of the following scenarios (x-axis and y-axis correspond to sequence length [22nt-30nt]):

#### Heterotypic ping-pong:

In this case, a strong ping-pong signal is produced by 24nt sequences and 29nt sequences (and vice versa). The different (*bona fide*) piRNA populations are presumably bound to different PIWI paralogs.

#### Homotypic ping-pong:

In this case, a ping-pong signature is produced by sequence pairs that are equal in size. Putative piRNA are presumably bound to the same PIWI paralog.

#### Two times homotypic ping pong:

In this case we can observe a strong 26nt-26nt ping-pong signature and a strong 28nt-29nt ping-pong signature. We can assume that, although two different populations of piRNAs are present, ping-pong processing bases on the interaction of identical PIWI paralogs.

#### 4.5 unitas.ping-pong.fas

This file lists all sequences that were found to produce a 10 nt 5' overlap with any other mapped sequence. Only available when using the option -pp.

### 5. Command line options

Allowed values for options: [s]=string, [i]=integer, [f]=floating point number

```
-i OR -input [s]          Name of the input file. You can use multiple input
                          files at once, e.g.:
                          -i file1.fas -i file2.fq -i file3.sam
                          Alternatively you can provide the name of a
                          directory that contains all of your input files,
                          e.g:
                          -i path/to/your/input/files
-s OR -species [s]       Species name. Use the binominal nomenclature with
                          genus and species separated by an underline, e.g.:
                          -s mus_musculus
-latest_ref              Force unitaz to download the latest database
                          sequences. Otherwise unitas will use previously
                          downloaded sequences (if available) from the
                          UNITAS_refdump folder.
-refdump                Create a reference sequence dump folder, download
                          species-specific reference sequences and QUIT.
                          This folder and sequences herein can be used for
                          later offline unitas runs.
-refseq [s]             Use an arbitrary number of additional files that
                          contain reference sequences in FASTA format. FASTA
                          headers should have the following format:
                          >ncRNA_type|ncRNA_name
-riborase               Find all rRNA-like sequences in your input file
                          by using a complete NCBI rRNA nucleotide collection
                          in addition to the available ncRNA data for your
                          species.
```

-trim Use this option to search for and remove any 3' adapter sequence in input files. There is no need to provide a specific sequence.

-trim\_minlength [i] Minimum allowed read length [nt] after removal of adapter sequence. Default=10.

-trim\_maxlength [i] Maximum allowed read length [nt] after removal of adapter sequence. Default=50.

-trim\_ignore\_5p [i] Ignore first n basepairs for 3' adapter prediction. Default=22.

-trim\_skip\_reads [i] Skip the first n reads when searching for frequent motifs. Default=10000

-trim\_check\_reads [i] Check n reads for 3' adapter prediction. Default=500000

-trim\_polyA Allow polyA tails to be recognized as 3' adapter. Useful when library was prepared with polyA-tailing rather than 3' adapter ligation.

-trim\_maxfinalbias [f] Maximum allowed 3' nucleotide bias after trimming. If this value is exceeded, unitas will trim further 3' positions. Default=0.8.

-quick Allow less mismatch. Equivalent to:  
-tail 1 -intmod 0 -mismatch 0 -insdel 0  
Faster, less memory usage, less sensitive.

-slow Allow more mismatch. Equivalent to:  
-tail 3 -intmod 2 -mismatch 2 -insdel 1  
Slower, more memory usage, more sensitive.

-tail [i] Maximum number of allowed non-template 3' nucleotides when mapping user sequences to reference miRNA (miRNA-precursor) and piRNA cluster sequences. Default=2. Summed values for -tail and -intmod must not exceed 5.

-intmod [i] Maximum number of allowed internal mismatches when mapping user sequences to reference miRNA (miRNA-precursor). Default=1. Summed values for -tail and -intmod must not exceed 5.

-species\_miR\_only Do not use miRNA (-precursor) sequences from other species when searching for miRNAs in input dataset. Default=off.

-mismatch [i] Maximum number of allowed mismatches when mapping user sequences to reference ncRNA sequences (does not apply to miRNAs and putative piRNAs). Default=1.

-insdel [i] Maximum number of insertions/deletions when mapping user sequences to reference ncRNA sequences (does not apply to miRNAs and putative piRNAs). Default=0.

-threads [i] Maximum number of parallel threads. Applies only if using more than one input file. Default=1.

-memory [i] Limit memory usage [GB] for SeqMap mapping. Default is no limit. When using a limit, unitas will quit before the limit will be exceeded.

-less\_memory Will use modified parameters for SeqMap mapping to reduce memory usage. Will increase running time.

-even\_less\_memory Will use modified parameters for SeqMap mapping to reduce memory usage even more. Will increase running time.

-phasi [i] Search for phased siRNAs (phasirRNAs or tasiRNAs) with specified length = [integer]. When using this option, the input file must be a map file in either SAM or ELAND3 format. You can use this option multiple times, e.g: -phasi 21 -phasi 24.

-na\_for\_phasi Only sequences without annotation will be considered for phasiRNA prediction.

-pp Analyze 5' overlaps of mapped reads to identify so-called ping-pong signatures (preference for 10 bp overlaps) which is a footprint of secondary piRNA biogenesis. When using this option, the input file must be a map file in SAM or ELAND3 format.

-keep\_temp Do not remove temporary files from data dump folder.

-skip\_mapping Skip mapping to reference sequences. Equivalent to:  
-skip\_miR -skip\_cdna -skip\_ncRNA -skip\_piR  
Use this when you want to trim 3' adapters and/or want to search for phasiRNAs only.

-skip\_miR Skip search for miRNA reads, search for other ncRNAs only.

-skip\_cdna Skip search for reads that map to Ensembl cDNA

```

sequences.
-skip_ncRNA      Skip search for reads that map to ncRNA collection.
-skip_piR        Skip search for reads that map to known piRNA
                  producing loci.
-skip_dust       Skip filtering low complexity sequences.
-dust_limit [f]  Threshold for fraction of a sequence that consists
                  of simple sequence repeats When filtering low
                  complexity reads from input files. Default=0.75.
-dust_max [i]    Maximum motif size for simple sequence repeats.
                  Default=5.
-dust_maxN [f]  Maximum fraction of Ns in a read. Default=0.5.
-noCCACheck     Mature tRNAs carry a CCA-3' which is enzymatically
                  added to tRNA transcripts unless it is present
                  already. unitas will check 3' termini of tRNAs and
                  add the CCA-3' unless this option is turned on.
-CC_is_CCA      Treat 3' tRFs with CC-3' as CCA-3'. Makes sense
                  when protocols for library construction use poly-A
                  tailing with subsequent A(n)-3' trimming.
-no_html        Do not output html files with visualization of
                  sncRNA annotation and analysis.
-diffexpr       Search for differentially expressed sRNAs across
                  different probes. Define 2 groups with a recommended
                  minimum of 2 probes per group using the options -g1
                  and -g2 as described below. When using this option
                  unitas will do the comparison and quit. Change the
                  name of the output file using the option
                  -diffexpr_out.
-diffexpr_t     Perform standard t-test (unpaired, two-sided).
                  By default unitas will calculate the Shared Area of
                  two Normal Distributions (SAND) derived from the
                  read counts of the two distinct groups and use it
                  as a proxy for p.
-diffexpr_p [f] Critical p value for differential expression
                  analysis. Default=0.05.
-diffexpr_acorrection [i] Correction of alpha error (multiple testing).
                  Allowed values are 0 (=no correction), 1
                  (=Bonferroni-Holm, default) and 2 (=Bonferroni).
-diffexpr_estdev [f] If one group comprises only one replicate, the
                  variance can be estimated by means of this factor
                  which is 0.05 by default. That means if sequence A
                  has 100 reads in the given replicate, unitas
                  virtually adds two replicates with read count values
                  105 and 95 (+- 5%).
-diffexpr_nostrays Only consider sequences that are present in all
                  replicates.
-g1 [s]          unitas output folder for probe assigned to group 1.
                  Use this option multiple times for every probe that
                  you want to assign to group 1. E.g:
                  -g1 UNITAS_04-01-2017_SRR123456.fasta_#1
-g2 [s]          Probes assigned to group 2 (see -g1).
-diffexpr_out [s] Specifies file names where the results of the
                  differentially expressed RNAs analysis will be
                  written to. Extensions .up1 and .up2 will be added
                  to the name. Default file names are:
                  'unitas.diff-expr.up1' and
                  'unitas.diff-expr.up2'.
                  (~.up1->higher expression in group 1, ~.up2->higher
                  expression in group 2).
-silent         Less console (STDOUT) output during annotation.
-supp_spec      Prints the complete list of supported species and
                  quits.
-h OR -help     Shows usage information and quits.
-show_options   Shows available options and quits.

```

## 6. Troubleshooting

We really tried hard to design `unitas` in a way that ensures compatibility with most platforms. Although we have tested `unitas` thoroughly on several different systems, we cannot guarantee that it will run on every machine on this planet. Here are some solutions for problems that may occur or have been reported by some users:

Command perl is not available.

You try to run the `unitas` Perl script but Perl is not installed on your computer (most likely you are on a Windows machine). You should try one of the following:

1. Use the precompiled executable file for your system instead of running the Perl script.
2. Download and install either Strawberry Perl or ActivePerl, both are freely available.

```
Can't locate LWP/Simple.pm in @INC [...]  
Can't locate Archive/Extract.pm in @INC [...]  
Can't locate File/Copy.pm in @INC [...]  
Can't locate File/Path.pm in @INC [...]  
Can't locate Getopt/Long.pm in @INC [...]
```

You try to run the `unitas` Perl script but the module `LWP::Simple` (or one of the other modules) is missing on your computer for some reasons. You should try one of the following:

1. Since version 1.3.0 we provide `unitas` within a zip compressed folder that contains all the required modules. Try to run version 1.3.0 or later inside the supplied folder.
2. Use the precompiled executable file for your system instead of running the Perl script.
3. Upgrade your Perl distribution with the following two commands:

```
cpan  
upgrade
```

4. Install the `LWP::Simple` module (or any other missing module) with the following two commands:

```
cpan  
install LWP::Simple
```

Failed to load current species list from smallRNAgroup-SERVER. Use internal list.

This message will occur if you are not connected to the internet or the `smallRNAgroup-SERVER` is down. In the latter case, `unitas` will use an internal list of supported species which is maybe not up to date. If you are not connected to the internet `unitas` can only use previously downloaded sequence data and will quit in case that there is no reference dump folder for the species in question in the current working directory.

Unable to create temporary file with list of data dump folders.

Unable to create dump folder for reference sequences.

This is most likely because you are on a Mac or Linux machine and do not have permission to write into the current working directory. You can change permissions with the following command (may require password):

```
chmod -R 755 /path/to/folder
```

No success when building SeqMap from source. Will download pre-compiled SeqMap version from smallRNAgroup-SERVER.

`unitas` tried to compile the downloaded `SeqMap` source code with `g++` but failed. Maybe the `g++` compiler is missing on your computer. `unitas` will download a precompiled `SeqMap` executable that should run on your system. However, it is likely that you have to change file permissions for that executable file manually (allow execution). Check subsequent `unitas` messages.

Permission denied. You have to change file permission for file 'seqmap.exe' manually.

`unitas` failed to compile the `SeqMap` source code and downloaded a precompiled version for your system. To execute this file, you have to change file permission manually (make this file executable).

Some people reported crabbled error messages when running one of the executable files that can look like this:

```
My-MacBook-Pro:mirna unitas me$ ./unitas 1.2.0 -input unitas.fa -species hsa  
Can't load '/var/folders/54/7cnshs5s2rq2scdmfk_y_m_r0000gn/T//par-506965727265/cache-

at /System/Library/Perl/Extras/5.18/PAR/Heavy.pm line 75.
```

```
Compilation failed in require at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/Handle.pm line 269.
BEGIN failed--compilation aborted at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/Handle.pm line 269.
Compilation failed in require at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/Seekable.pm line 101.
BEGIN failed--compilation aborted at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/Seekable.pm line 101.
Compilation failed in require at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/File.pm line 133.
BEGIN failed--compilation aborted at /System/Library/Perl/5.18/darwin-thread-multi-2level/IO/File.pm line 133.
Compilation failed in require at -e line 351
```

We believe that this comes from a conflict of modules packed into the executables and modules that are installed on the computer. In all reported cases, no error occurred when running the Perl script rather than the precompiled executable.

## 7. Citation policy

Sequence annotation with `unitas` is not possible without having reference sequences. `unitas` uses reference sequences from different public online databases. When you use `unitas` for sequence annotation, please cite the papers listed in 3.1.4. as well as the SeqMap paper from Jiang and Wong (see 3.1.5) in addition to `unitas`.

You can cite `unitas` as follows:

Gebert D, Hewel C, Rosenkranz D (2017). `unitas`: the universal tool for annotation of small RNAs. *BMC Genomics* 18(1):644.

## 8. Contact

If you have any questions or comments or found any bugs in the software, please do not hesitate to contact us:
